

Reference: Nursing Cows

Product: Animal Biosa (silage additive)

Animal: 40 limousin dam + breeding

Crops: Grass (silage in round bales on 50 ha)

Country: Denmark

Contact: lene@biosa.dk

Purpose: Production of wrap-grass (main fodder) of good quality.

Dosage: Animal Biosa is spread with a sprayer onto the freshly cut grass (1 litre per ton) per ton grass just before it is raked together and pressed. Besides, the remedy is used on straw bedding in the stable.

Results: A high quality ensilage. Even in the summer, an opened round bale (750 kg) stays fresh for between 10-15 days after opening. The animals eat the ensilage with pleasure and satisfaction. They have remarkably fewer liver abscesses than before. The decomposition in the belly is more effective now than before the ensilage was treated. The animal's faeces are much more crumbled than before and there is no undigested hay and straw anymore. Even the people from the tractor station have noticed it. It takes less time to treat the manure before it is spread on the fields. And this of course is also an expenditure cut, which abundantly covers the expenses for buying the product.

Lactic acid bacteria surely are beneficial the whole way through. First, regarding the ensilage, which reaches a higher quality and then, in the animals belly. Finally, on the fields where the soil benefits from that the manure already is composting when it is brought out.
